

Still considerable avalanche danger at high altitudes

Danger Level 3 - Considerable

Tendency: Decreasing avalanche danger
on Wednesday 14 January 2026

Wind slab

1800m

New snow

1800m

Considerable avalanche danger at higher altitudes

Avalanche danger is considerable above 1800m, moderate below that altitude. The main problem is the fresh fallen and drifted snow. One single winter sports enthusiast can trigger small-to-medium sized slab avalanches in wind-loaded zones, particularly on steep NW-E-SE facing slopes and in gullies and bowls. In zones with rain impact, increasingly frequent wet snowslides and avalanches will also be possible during the course of the day.

Snowpack

Widespread 20-30cm of fresh snow is anticipated. It will be transported by intermittently strong westerly-to-northwesterly winds. The fresh snow and fresh snowdrifts since Thursday often lie deposited on top of a loosely-packed, faceted, expansively metamorphosed old snowpack surface or atop surface hoar. Thus, bonding is poor. In addition, layers inside the fresh snow and freshly generated drifts are also prone to triggering.

Weather

Nocturnal hours: heavy, intense snowfall down to low altitudes. Sunday: impeded visibility due to low lying clouds and snowfall. Later on, it will become drier, clouds will disperse somewhat. Temperature at 2000m: -11 degrees; at 3000m: -17 degrees. Moderate to strong-velocity northerly winds at high altitudes.

Tendency

Avalanche danger receding only slowly
