

Danger Level 1 - Low

Tendency: Increasing avalanche danger
on Saturday 3 January 2026

Low avalanche danger will prevail. Wind slabs require caution.

The somewhat older wind slabs represent the main danger. These are small. Afternoon: As a consequence of new snow and wind, sometimes avalanche prone wind slabs will form in the west and in the northwest. The avalanche prone locations are to be found in particular on very steep shady slopes at elevated altitudes and adjacent to ridgelines.

Apart from the danger of being buried, restraint should be exercised in particular in view of the danger of avalanches sweeping people along and giving rise to falls. In the afternoon sometimes avalanche prone wind slabs will form in particular in the west and in the northwest.

Snowpack

Some snow will fall in particular in the west and in the northwest. The wind will be strong in some regions. The old snowpack is faceted, especially on west, north and east facing slopes at elevated altitudes.

The snowpack will be subject to considerable local variations. Less snow than usual is lying in all altitude zones.

Tendency

As a consequence of new snow and wind there will be only a slight increase in the avalanche danger. This applies in particular in the west and in the northwest.
