Danger Level 1 - Low

Danger of falling!

The avalanche risk is low. Smaller avalanches can be triggered in persistent weak layers, especially with large additional loads. The few avalanche prone locations are found on extremely steep slopes in the northern and eastern aspects, especially when entering gullies and bowls.

Snowpack

Up to high altitudes, the snowpack has crusted can form on the surface. At higher altitudes, bonded snow lies on angular snow layers in places. The often hard-frozen snowpack barely softens during the daytime changes. Especially on sunny slopes, large areas will be bare again. Overall, there is little snow and ground contact is to be expected everywhere.

Tendency

The avalanche danger remains low.
