Danger Level 2 - Moderate

Wind slabs are prone to triggering in places.

The avalanche risk is moderate above the tree line and low below it. In places, wind slab can be triggered as a small or medium slab avalanche by a small additional load. Avalanche prone locations are located adjacent to the ridgeline, crest or summit in steep terrain in northern and eastern aspects as well as in gullies and bowls. The number and extent of avalanche prone locations increase with altitude. In addition to the risk of burial, the risk of being swept away and falling must be taken into account.

Snowpack

Older wind slabs are sometimes prone to triggering on surface hoar or graupel. Snowdrift accumulations and obstacles are often covered by a thin layer of soft new fallen snow and are therefore difficult to recognise. Below the old melt-freeze crust, faceted crystals can often be found right down to the ground, especially at high altitudes. On the south side, there is insufficient snow for winter sports right up to the higher altitudes.

Tendency

No significant change until the weather changes on Thursday.
