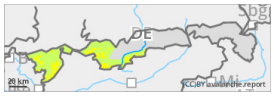
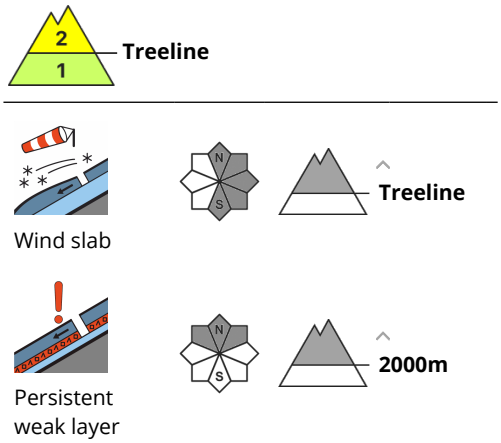
Danger Level 2 - Moderate





Watch out for weak layers deep in the snowpack!

The avalanche risk is moderate above the tree line and low below. Fresh wind slab is the main problem. Avalanches can be triggered in places with a small additional load. This is possible above all in the steep terrain adjacent to ridgelines in the north, east and south aspects as well as in gullies and bowls.

On shady slopes at higher altitudes, avalanches can break through to deeper layers in the persistent weak layer and reach medium size.

Snowpack

Fresh snowdrift accumulations form with winds from north-westerly directions. Some of these come to rest on a soft layer of snow and can be prone to triggering. In shady high altitudes, layers of faceted crystals can be found deep in the otherwise compact old snowpack. At medium altitudes, the snowpack is wet towards the ground.

Tendency

Depending on the amount of new snow, the avalanche risk may increase slightly.
