Danger Level 1 - Low

Be aware of the risk of falling on hard frozen surfaces.

The avalanche risk is low. Smaller avalanches can be triggered in persistent weak layers, especially with large additional loads. The few avalanche prone locations are found on very steep slopes in the northern and eastern aspects, especially when entering gullies and bowls.

Snowpack

Up to high altitudes, the snowpack has crusted can form on the surface. At higher altitudes, bonded snow lies in places on angular, built-up layers. On the sunny slopes, the hard-frozen snowpack softens on the surface during the daytime changes. Larger areas here are already bare again. Overall, there is little snow, ground contact is to be expected everywhere.

Tendency

The avalanche danger remains low.
